REPORT ON SITE EXAMINATION

LOWER NORTH-EAST ROAD, PARADISE.

for

South Australian Browing Co. Ltd.

...

#### INTRODUCTION

A site examination has been carried out for the South

Australian Brewing Co. Ltd., for a proposed hotel on Lower North
East Road, Paradise.

The examination was requested by the applicant on 30th September, 1964.

Two test holes were dug to a depth of 6 feet (Holes 1 and 2) and both have been geologically logged.

This report describes the results of the logging and discusses the foundation characteristics of the materials encountered.

#### SOILS SHOWN IN TEST HOLES

Soils at the site are alluvial clays and represent essentially type RB3, the dominant soil type of the Urrbrae Association, as mapped within the Adelaide area.

A thin sand horizon I foot thick overlies red-brown clay which is coarsely structured and shows mainly vertical fissuring. Below 2.5 feet the clay contains abundant lime up to 30% of the total volume in parts, decreasing to less than 10% near the base of the test holes. The profile is also very sandy below 2.5 feet.

#### FOUNDATION CHARACTERISTICS

The sanda horison from the surface to I foot is quite compacted but unsuitable for foundations of the proposed building.

Below 1 feet, and extending to 2.5 feet below surface, the red-brown clay is noticeably structured and is subject to severe seasonal swelling and shrinking movements due to reaction of the clay minerals present when water is absorbed or evaporated. These movements can produce strong forces and the vertical component at the surface can be as much as 1.5 inches. Failure in shallow feetings of inadequate strength is quite common.

Underlying the red-brown clay are limey clays which would be subject to less severe movements of the same nature.

Compressive strength (qu) values obtained by Soiltest
Penetrometer range from 0.75 tons/sq.ft. at a depth of 2 feet in

the red-brown clay to >4.5 tons/sq.ft. in the lower, more limey and sandy clays. Most consistent figures between 3.5 and 4.5 tons/sq.ft. were obtained at approximately 5 feet below ground surface in both test heles. At this depth, a marked increase in the sand fraction and decrease in lime is noted.

#### - FOOTING CHARACTERISTICS

It is suggested that footings would be best seated at least 5 feet below ground surface. At this depth, shrinking and swelling movements would be much smaller than at the surface and bearing capacity should be higher, especially during wet periods.

#### GROUNDWATER

No groundwater was struck in the test holes. Records from a nearby bere indicate a groundwater table at about 60 feet below ground surface.

A temporary perched water table is likely to occur during the winter period, the maximum depth of wetting probably extending to approximately 7 feet below surface.

#### GENERAL RECOMMENDATIONS

All surplus surface water, downhill drainage, roof run-off etc., should be carried well away from the footings in properly constructed drains of adequate capacity. Lawns and gardens should be kept well clear of the foundation area to prevent damage resulting from everwatering.

A wide concrete, or heavy asphalt paving completely surrounding the building will minimise soil moisture variations beneath the footings.

If a concrete paving is used it should be bonded to the footing by means of a bitumastic compound.

The suggestions regarding types of footings are intended as a guide to the foundation characteristics of soils at the site. Alternative designs are not necessarily excluded by the suggestions made in this report.

## APPENDIX A

DATA ON SOIL TYPE RB3

### SOIL TYPE RB3

The following soils data is reproduced from Department of Mines Bulletin No. 32: The Soils and Geology of Adelaide and Suburbs, by G. D. Aitchison, R. C. Sprigg and G. W. Cochrane.

The information is offered as a general guide and may not apply in all respects to the soil examined.

For a full discussion the reader is referred to Bulletin 32 and to other publications quoted therein.
