## DEPARTMENT OF EMILES EQUIL AUTHALIA

Rept.Bk.No. 73/199 G.S. No. 5204 D.H. No. 449/73 Img.Geol.Ho. 1973/13

DEPARTMENT OF MINES HEAD OFFICE, CLINSIDE Section 264, Hundred of Adelaide REFORT ON FOUNDATION INVESTIGATIONS Client: Public Buildings Department

#### SUPPLANY AND CONCLUSIONS

Interpretation of drilling results indicates the following sequence:

- 0 5 metres Surface materials and Fill.
- 5 30 metres Hindmersh Clay equivalents.

Aurface materials are prone to seasonal volume changes and any structure founded in these materials should be isolated from the main structure. Fill is unsuitable for foundations.

A suggested founding level for the main structure is indicated within the Hindmarsh Clay equivalents. Gravels at this level are almost certainly lensoidal and some piles may terminate in or near to silts or clays. Laboratory testing is recommended to ensure that these silts and clays will not be overstressed.

Basements will be below water level for at least part of the year.

Paths, pavements and grounds should be laid out to ensure that the natural moisture regime of the site is not unduly disturbed. Paths and pavements may require undercutting.

#### INTRODUCTION

Three cable-tool holes have been drilled to investigate foundation conditions for the proposed new Department of Mines Head Office, Parkside. Location details are shown on figure 1. There appropriate, standard penetration tests were performed at nominal 1.5 metre intervals, and sealed tube samples were recovered for subsequent laboratory testing.

All three bores were completed with perforated p.v.c.
liners and remain available as water level observation bores.
Logs of bore holes and explanatory notes form appendix 1.

#### **TOFOURAPHY**

The site alopes gently down towards & Block and is grassed. Considerable filling has apparently taken place edjacent to the Australian Mineral Foundation but both the extent of this filling and the original ground contours are unknown.

Surface drainage is poor and during wet weather the ground surface becomes extremely soft and wet.

#### SIVE GEOLOGY

Site geology, as interpreted from the Grill core, is summarized in table 1 and illustrated in the geological cross section (Figure 2).

the second of	_	and the second second	 	Alternative and Changes and are all the san about
PARTE	4	SIMMANY	GEOLOGICAL	SHECKSSTON

Unit	Thickness	Dominant Materials	Age
Surface Natorials.	4.5 - 5.0 metres	Clays, silts, sands. Fill in CH1.	Pleistocene to Recent.
Hindmarsh Clay Equivalents.	26 metres +	Silte and clays with sand and gravel lenses.	Pleistocene.

## A. SURPACE NATERIALS

Clays (CL-CH)\*, silts (ML) and sands (EM-EC) of low to moderate strength. Poorly consolidated fill in CH2.

Bores CH2 and CH3 encountered approximately 5 metres of sands, silts and clays of low to moderate strength. The clay horizon has the characteristics of a red-brown earth profile (Taylor 1970). Subsoil lime content is moderate.

Bore CH1 encountered 5 metres of poorly consolidated fill - a mixture of black and dark brown sandy silt with minor clay, containing fragments of brick, concrete, ceramic and quartzite. At least some of this fill appears to be cinders.

## B. HINDWARSH CLAY MAUIVALEDES

Silts (MI-NH), and clays (CL-CH), with interbedded lenses of sand (SM-SC) and gravel (GM, GP, GC).

All three bores encountered a sequence of silty clays and clayey silts with interbedded silty sands and gravels, here correlated with the Hindmarsh Clay of Pleistocene age.

<sup>\*</sup>Terms in brackets are defined in Appendix 1.

Silty clays and clayer silts are stiff, grey, generally humid to damp, and occasionally sandy.

Sands and gravels are medium dense to dense, composed of engular to sub rounded strong to medium strong quartiste, generally in a silty or occasionally clayey matrix. Examination of similar materials exposed in investigation trenches on the site of the proposed new core library show that these gravels may range up to 15-20 cms in diameter and that they occur as discontinuous lenses within the silts and clays.

## C. GROUNDWATER

Water was encountered in all bores at the levels shown on the cross section (Figure 2). No significant flows were recorded. Although water levels did not rise measurably during the 15 minute stabilisation period allowed during drilling operations, final levels rose to within two metres of ground level.

#### FOUNDATION CONDITIONS

## A. SURFACE MATERIALS

Surface materials are considered suitable as foundations for comparatively lightly loaded structures only. Bearing strengths are low to moderate and the clay horizon, which has the characteristics of a red-brown earth (RB3), is probably subject to considerable seasonal volume changes. It is strongly recommended that any structure that may be founded in or on these surface materials (e.g. annexes, floors, pavements), should be structurally isolated from

the main structure, and that allowance should be made to accommodate any movements that may occur.

The fill encountered in bore CH1 is poorly consolidated and is considered unsuitable as foundations for any structure. Chould it prove necessary to found any structure in this fill, undercutting and replacement with a sufficient thickness of suitably compacted material is essential.

## B. HINDMARSH CLAY EQUIVALENTS

Standard Penetration Tests indicate that silts and clays have moderate strength. Long term settlements are unlikely provided stresses are not excessive.

Gravels and sands are dense to medium dense and probably have moderate to high strength. However, Standard Penetration Tests in these materials cannot be regarded as reliable due to the possibility of a coarse fragment choking the entry to the spoon and presenting an excessively high resistance to penetration. These materials may densify and settle slightly under load but vibrations accompanying pile driving should cause some densification and reduce subsequent settlement. Long term settlements in these pervious gravels and sands are unlikely.

A suggested founding level is indicated on the geological cross section (figure 2). Thile correlations between bore holes appear reasonable, it is stressed that the gravels and sands are almost certainly lensoidal and it is recommended that a substantially thinner gravel horizon should be assumed in design calculations.

Some piles could terminate in or near to silts and clays and the strength of these materials is suggested as a safe design assumption. Laboratory testing of these silts and clays is recommended to ensure that safe values of shear strength and settlement will not be exceeded. Allowable settlements should be maintained as low as is possible to ensure that significant differential movements do not occur.

## C. GROWINGARIN

silts and clays at the suggested founding level are relatively impervious and are unlikely to undergo significant changes in moisture content under natural conditions. To avoid the possibility of softening and loss of strength it is important that no water should be allowed access to these materials via excavations, foundations or services.

Larked seasonal water level fluctuations are likely within the Surface Deposits. Since static vater level at the completion of investigations was within 2 metres of ground level it is probable that any basement will be at least partly below water level during winter. Adequate precautions must be taken to ensure that besedents remain dry.

## SCHOOLD

Care should be taken in laying out grounds to ensure that the moisture regime under foundations and pavements is not unduly influenced by concentration of surface run-off, watering of lawns and gardens, or by the growth of tree roots. Lawns are likely to become unduly soft and wet during winter months and adequate paths should be provided along all likely major traffic routes.

Pavements and paths, particularly rigid pavements, may be affected by seasonal volume changes in the red-brown earth soil profile and undercutting and backfilling with suitably compacted fill is recommended.

## Sealed Tube (LB) Samples

Sealed tube samples, for laboratory testing, are taken at various intervals during drilling. These are obtained by driving an "L" type sampling tube with a Mark B cutting shoe (Fig. 4) a distance of 30 cm into the material to be sampled.

Before the sample is taken the hole is cleaned out to the depth specified. The hole is not reamed or cased for at least 30 cm from the bottom, however, because these operations can cause considerable disturbance in the soil below. The sampling assembly is lowered carefully to the bottom of the hole, the sampling tube driven exactly 30 cm, and the number of blows recorded.

The sample is sealed in the tube by inserting in each end, plastic seals with rubber sealing rings, and the tube is then labelled and stored in a Laboratory Sample Box.

LB sampling equipment is a composite sampler for obtaining samples with the least possible disturbance. Details are as follows:

Sampler tube - ASSAB tube cadmium plated "L" type 10.2 cm (4.016 in.) I.D. 10.9 cm (4.282 in.) O.D.

Mark B shoe - ASSAB tube, heat treated, cadmium plated Area ratio 15%
Inside clearance - 0.4%
Outside clearance - nil
Cutting edge angle - 7°

## Standard Penetration Test

The Standard Penetration Test (Terzaghi et al 1948) is used to test the in-situ density of sands and to give an indication of the consistency of clays, and compactness of silts. However the test results can be affected by several geological factors such as degree of cementation, and size and shape of grains. These factors should be taken into account in interpretation of results.

The equipment is illustrated in Fig. 5 and consists of a 5.1 cm (2 in.) diameter, sampling spoon (tube) and a hammer of standard weight (64 kg (140 lbs)).

#### APPENDIX

### LOGS OF CABLE TOOL HOLES AND EXPLANATORY NOTES

## NOTES ON DRILLING PROCEDURES

## Equipment

The drilling is carried out with a cable tool drilling plant using sampling tubes attached, through a vacuum head, to the sampling tools (Figs. 1 and 2).

# Sampling Procedures S.A. Samples

To obtain, for logging purposes, an almost continuous series of samples, with a relatively small amount of sample disturbance, SA type samples are taken. These are obtained by driving an "S" tube, fitted with a Mark A shoe (Fig. 2), into the material to be sampled.

The assembly is lowered carefully to the bottom of the hole, and the tube driven exactly 30 cm, and the number of blows required for the 30 cm of penetration recorded.

The sample, or core, is extruded from the sampling tube using an hydraulic ram. The extruded core is sealed in a labelled plastic bag and stored in a core box (Fig. 3).

The hole is reamed with a "D" or "E" shoe (Fig. 2) and then the next sample is taken, using the same procedure as above. Thus the hole proceeds by alternate sampling, reaming (and where required, casing) operations, and the samples form a continuous record of the materials penetrated except for a few centimetres which may be lost between samples during reaming operations.

SA sampling equipment is a composite sampler for simple class sampling. Details are as follows:-

## "S" SERIES CUTTING SHOES

MARK	FEATURES	USĖS
A	Inside clearance 3%. Area Ratio 33%.	Continuous open-tube sampling in strong soils, in which it causes little deformation. Samples extruded and used for logging purposes. Hole is reamed after each sample.
D	Shoe belled out to 12.5 cm (4 29/32 in.) (just greater than outside dia. of vacuum head)	Continuous open tube sampling where considerable deformation of sample is permissible. Essentially self-reaming.

With the equipment assembled as in Fig. 5 the hammer is allowed to fall on to the drill rods until the sampling shoe has penetrated 15 cm into the soil. The Standard Penetration Test is the number of blows (N) required to produce the next 30 cm of penetration.

#### NOTES ON DRILL LOG SHEETS

The logs are plotted on a standard cable-tool log form.

Near the centre of the form a graphic log of the materials encountered is shown.

In the column to the right of the graphic log, the soils are classified and described according to the Unified Soil Classification (U.S. Dept. of Interior, Bureau of Reclamation 1966) as shown on Figure 6.

To the left of the graphic log is a geological description of the materials sampled. This includes:-

...Organic materials

Water levels are indicated by a small arrow with the date at which the observation was made.

In the blows per 30 cm column, a continuous histogram is made of the number of blows required to drive the sampling tube through each 30 cm of material. A hatching code is used to distinguish various types of sample. This code is reproduced at the bottom of each log sheet.

In the column on the far right of the log sheet, readings of unconfined compressive strength (qu) made with a Soiltest Penetrometer, are recorded. The readings are plotted as a histogram. The Soiltest Penetrometer only gives true values of qu when used in clays in which  $\emptyset$  = 0.

#### 1. INTRODUCTION

This report with accompanying drawings and model is submitted as the proposal for a new office building for the Department of Mines at Glenside as part of the Australian Mineral Sciences Centre.

The scheme has been prepared in accordance with accommodation schedules and design requirements as outlined in the brief prepared by the Public Buildings Department and with consultation with officers from the Department of Mines. Additional accommodation requested by the department is noted in the schedule at the end of this section of the report.

The scheme as presented does not indicate detailed planning of the particular floors. Functional planning to determine the optimum floor size and area in relation to the disposition of departments and sections has been carried out and appears in the schedule. Although final layouts have not yet been determined the estimate includes allowances for all partitioning of all the floors based on work done to date.

#### 2. THE SITE

The site at the Mineral Sciences Centre at

Glenside is between the recently completed

Natural Gas Pipeline Authority and the

Australian Mineral Foundation, currently under

construction.

On Commission from the Public Buildings

Department, this office prepared a master

plan for the centre determining the

approximate disposition of the proposed buildings

and laying out the network of roads and parkings

areas for the whole site.

Concurrent with this submission is our proposal for the Core Library for the Department of Mines. This complex is sited on the north-west corner of the site. The site allocated for the office building lies between the service ring road and visitors entry loop road, on a tract of land between the two other buildings that is being developed on a segregated pedestrian "campus" concept.

#### 3. BUILDING PROPOSAL

This proposal is for a seven storey building, of square plan form with service cores set into the north-west and south-east corners.

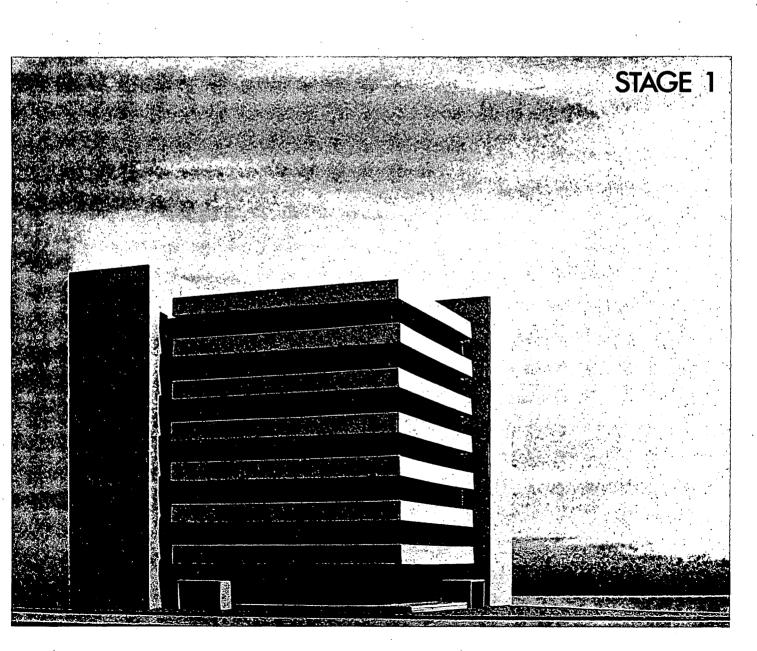

Influencing factors which led to the evolution of this concept were:-

- Sciences Centre as set out in the master plan, the site available for the Department of Mines office building is limited. The open spaces between the buildings must be sufficient in size to be properly landscaped and be meaningful in terms of the "campus" concept.
- Existing buildings and the proposed core
  library are of one and two storey construction.

  In terms of massing of buildings in the Centre
  it is desirable to have a taller element as
  a balance to the setting. The office accommodation provided by this building is appropriately
  expressed as a multi-storey structure.
- The Department is made up of many interrelated sections. Analytical studies were made to determine near optimum floor areas to provide best disposition and grouping of sections and internal communication.
- The expressed desire to adopt office
  landscaping principles where appropriate
  influenced the plan area and form which is
  best resolved in a multi-storey building.

Consideration was given to providing the accommodation in a three level building as suggested in the brief also in two which is more reasonable if no lifts are provided.

However, the parameters and criteria, with their influences are best met with a multistorey building, which is our recommendation in this proposal.

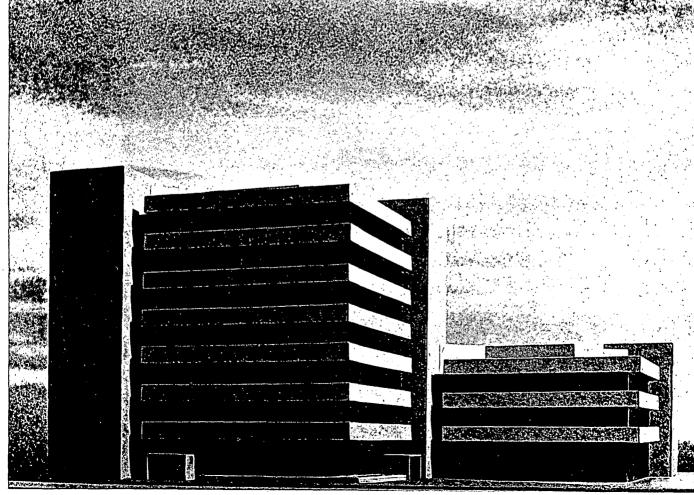

#### 4. EXPANSION

The brief requires that provision be made for expansion of the Department. Stage one allows for some expansion within the building by taking up excess space allocation and efficient utilization of office landscaping. Within twenty years a further 18,000 square feet of office accommodation is proposed as the second stage when a major reallocation of space will be made.

Careful consideration has been given to alternative possibilities for the second stage. Vertical expansion and additional wings were rejected in favour of a linked annexe building.

The annexe is envisaged as a three storey building, identical in plan form to the first stage linked into and sharing the N - W corner core. The lift lobby will provide a link between the buildings at each level. The lift service has been designed to handle the additional load of the annex without diminishing the performance. Provision is also made in Stage 1 for a duct for air conditioning service to the annex.

Although the brief stipulates a specific figure for the additional area, the proposal presents a flexible solution. With some modification to the core any number of floors could be accommodated in the second stage development.

#### 5. PLANNING

The plan form is basically an 84'0" square with two 26'0" square service cores set on diagonally opposite corners. One core contains toilets, stair, cleaners and tea room and the other the lifts and second stair. This core is planned to allow linking with the proposed annexe extensions. Both cores provide for mechanical and electrical services.

A 4'0" planning module has been adopted with window mullions aligning with this grid to give partitioning flexibility at the window wall. A staggered pattern of 1'4" wide light fitting in the middle third of the 4'0" module gives ultimate flexibility of moving partitions without having to move light fittings.

The 4'0" module is compatable with the preferred metric multimodule of 1200 m.m. The Metric Conversion Board is recommending that for dimensional co-ordination, a basic module of 100 m.m. be adopted, with preferred multi-modules of 300, 600, 900, 1200 m.m. etc. The soft conversion of 4'0" is 1219 m.m.

The plan form allows for several planning approaches.

Conventional double corridor layouts are possible with offices on the window walls with an internal zone for storage or special use. The large open floors are ideally suited for office landscaping. The square 84'0" plan is also suited to having some offices on the north and south walls and still have a broad enough

floor for office landscaping. This approach is seen as being most appropriate for several of the floors.

There is a predominant bias to a male population in the Department. The toilet accommodation is planned with the cubicles in the adjoining male and female toilets to be in line so that on any particular floor the partition can be located to suit the make up of the population of that section.

The mechanical plant room is located on the roof of the building. It is recognised that the plant can be a source of excessive noise to the top floor of the offices. Items of plant that constitute the greatest hazard are located over one service core with the air handling plant on the roof enclosure, suitably isolated from the structure to minimize excessive noise.

At this stage no provision has been made for staff recreation areas as it is envisaged that this will be one of the facilities provided in common to the Mineral Sciences Centre in the amenities building, presently the 'Y-block'.

To summarise, it is recognised that flexible accommodation is essential in planning to the Department as its complexion is constantly changing. To this end every endeavour has been made to present a solution that provides a great degree of flexibility in planning and use.

## 6. ACCOMMODATION SCHEDULE

The schedule below sets out the accommodation as set out in the brief and also shows where additional space has been requested and has been included in the planning. The schedule also shows what accommodation is provided on each floor based on planning studies done to date.

ACCOMMODATION (AS PER BRIEF)	PROPOSED ADDITIONAL AREA
1. GROUND FLOOR correspondence-gen.counter 1,38 registration 24 editorial & technical inf. 62 supply 30 museum & mineral display 1,40 study cubicles 48 sub total 4,42	10 20 00 00 30

## 7. ESTIMATE SUMMARY

The complete estimate and cost plan prepared by Crisp, Kavanagh & Partners is submitted under separate cover, this summary is an extract from their report

Building works

881,260

Engineering Services

1. Mechanical & air conditioning 241,833

2. Electrical & Thermal fire

alarm system 112,069

Lifts 88,475

Total \$1,323,638

10% contingency 132,363

Total \$1,456,001

The anticipated cost increases in wages and materials up till March, 1973 have been included in the above figures.

- 8. MECHANICAL AND ELECTRICAL ENGINEER'S REPORT.
- 8.1 MECHANICAL SERVICES
  - (a) Air Conditioning:

The basis taken for air conditioning design is as follows:-

Outside conditions - summer 100°F D.B. 70°F W.B. winter 45°F D.B.

Inside conditions - summer 75°F D.B. winter 70°F D.B.

Occupancy - One person per 80 sq. ft. floor area.

Fresh air - 15 c.f.m. per person minimum.

The perimeter areas of each floor to a depth of 12'0" will be served by a variable volume dual conduit system with separate air handling units for the primary and secondary air.

The internal areas of each floor will be served by a single duct variable volume system.

A minimum of six separate controlled areas per floor is envisaged the final arrangement being dependent on the ultimate occupation.

The internal zone conditioner and perimeter secondary air handling unit would be capable of using 100% outside air whenever the air temperature is suitable in order to provide to provide good operating cost economies.

All air handling equipment is located at roof level over the centre of the floor area with equipment and ductwork suitably isolated from the structure.

The refrigeration plant will be of the direct expansion type with two compressors and prime surface evaporative condensers located at roof level over one service core.

Two hot water heating boilers will be provided and located with the air handling plants. Boilers will be oil or gas fired as decided from final tariff information.

Each compressor and boiler will have a capacity of not less than 60% of the peak load requirements.

Return air will in general be taken back through the false ceiling space in order to minimise the necessity for grilles in walls and doors.

## (b) Ventilation:

An exhaust system will be provided for toilets, cleaners and tea rooms etc.

A plenum system will serve the lift motor room.

#### (c) Hot Water:

Hot water will be provided by means of a calorifier serviced by the heating boilers detailed in (a) above.

## 8.2 ELECTRICAL SERVICES

Main 415/240 volt supply will be taken from an ETSA supply point of an external pad-mounted transformer unit and the main switchboard will supply both the Office and Core Library buildings. Sub-main cables will provide supply to the Distribution Boards at each floor, the Mechanical Services switchboard and the Lift Motor Room board.

General office lighting will employ recessed

fluorescent units with hinged flat sheet prismatic

diffusers to provide open area levels of illumination

better than 550 lux. Each luminaire will be capable

of fitting an additional tube to provide for loss of

illumination should the areas be divided by full

height partitions.

Emergency lighting from storage batteries will be installed in the stairways and at key locations at each floor.

General purpose outlets will be installed throughout the building to serve office requirements, cleaning services and special purposes called for by the Client.

Final sub-circuit cabling will be protected by the miniature circuit breakers on the distribution boards.

External lighting will be installed at entrances and the service and parking areas. The selection of units and their location will be co-ordinated with the external lighting of adjacent buildings.

The fire alarm system will employ the electropneumatic detectors to operate local and
fire station alarms.

For the building telephone services, a main distribution frame will serve two intermediate distribution frames on each floor, through two riser systems of block cabling. Wall boxes, with draw-wires for cabling by the P.M.G., will be installed on Columns and perimeter wall. It is expected that the Client will grange for all facility cabling from the intermediate frames.

#### 8.3 COST ESTIMATES

The preliminary estimation of cost for the above services are:-

Mechanical \$205,000.00

Electrical \$95,000.00

#### 9. STRUCTURAL ENGINEER'S REPORT

The structure consists of reinforced concrete construction generally with steel framed construction used only for the plant room at main roof level and in the roof over the service cores.

Floors are of flat slab construction with drop panels at columns. Service core walls will generally be load bearing reinforced concrete with external finish as off form concrete to suit the Architect's requirements. The external wall to the N-W core has been designed to allow openings into any future extension.

Footings at this stage are provisional and are subject to the results of a thorough site investigation. They are based at present on a permissible bearing pressure of 3 kips per square foot at a depth of 5'0" below ground level.

Preliminary borings done on 23rd November, 1972, indicate fill material up to approximately 16'0" to 17'0" deep at the Southern end of the present building location on site. This filling extends about 15'0" Northwards from the South side of the building. It would be beneficial to resite the building 20' - 25' Northwards from the present location.

The preliminary holes indicate silty, sandy soils overlying gravel at varying depths from 7'0" to about 17'0" below ground level. We are advised

'that perched water tables will probably exist in the upper zones down to the gravel. (Probably old creek bed).

The indications are that footings will need to be based on the gravel provided that the depth of same is adequate and that the soils underlying the gravel are firm.

For the present we suggest that the provisional design be used for estimating but that a contingency of \$10,000 be allowed against the need for deeper based footings.
