Your ref. | Our ref. JHH/ec | Date 10th May, 1976.

Subject: EL 221 - Work Summary and Future Programme.

Dear Sir,

The following details summarize work to date and proposed future work by Preussag Australia Proprietary Limited on EL 221.

1. Statistical Summary.

a. Geochemistry (number of samples):

stream sediment	soil	rock chip
121	723	65

- All analyses by A.S.C. Laboratories Pty. Ltd., Unley, S.A., for Preussag Australia Pty. Ltd.

- Soil sampling carried out by Ashton Exploration, Port Elliott, S.A., and Preussag personnel.

b. Gridding: 14,800 line metres gridded on 200m x 50m basis surrounding the old Perseverance-Bonaventura mine workings.

Gridding carried out by Ashton Exploration, Port Elliott, S.A., and Preussag personnel.

c. Geology: Reconnaissance over E.L. utilizing 1:50,000 and 1:25,000 air photo coverage.

Detailed mapping of the Perseverance-Bonaventure grid (supplemented by 1:5,000 air photo coverage).

.../2

Telephone: (03) 654 4955
654 4867
Telex: 32156

1. Statistical Summary (cont'd).

d. Geophysics: 7,000 line metres of Perseverance-Bonaventure grid covered by preliminary ground magnetic survey (total magnetic intensity).

Ground magnetic survey carried out by Ashton Exploration, Port Elliott, S.A., for Preussag Australia Pty. Ltd.

e. Petrography: 10 rock sample description by Ian R. Pontifex & Associates Pty. Ltd., Rose Park, S.A., for Preussag Australia Pty. Ltd.

f. Field Work by Preussag Personnel to Date:

1 geologist - 4 weeks.
1 field assistant - 5 weeks.

Plus two inspections of portions of the E.L. by Head Office and local office personnel - 6 man-days.

Plus contractor, P. Ashton of Ashton Exploration - 3½ weeks.

2. Results to Date.

The initial work by Preussag Australia Pty. Ltd. on EL 221 assessed the results of exploration by former explorers in the area and outlined a Pb-Zn soil anomaly around the old Perseverance-Bonaventure mine workings. Additional "infill" soil sampling and geologic mapping of the Perseverance-Bonaventura prospect have recently been completed (mid-April), together with geological reconnaissance in other areas within the E.L. All results of this recent work have not yet been received.

The soil anomaly outlined has approximate dimensions 1 km. east-west and ¼ - ½ km. north-south as determined by the 200 ppm Pb contour. The anomaly is located in a meta-sandstone-phyllite/metasiltstone sequence which is intruded by a number of thin (to ?5 metres), finely crystalline and brecciated quartz veins which appear to mark fault zones. The veins contain trace to minor amounts of galena, sphalerite, pyrite and chalcopyrite. Old, shallow workings on, or near, the veins occur in a number of localities within the gridded area.

.../3

3. Proposed Future Work by Preussag Australia Pty. Ltd.

a. Completion of the initial phase of exploration (geology, geochemistry) on the Perseverance-Bonaventura prospect when all results are available.

b. Should work in phase (a) prove encouraging, an I.P. will be completed.

c. Should work in phase (b) prove encouraging, a two-hole diamond drilling programme will be planned.

d. Additional exploration along the Cygnet-Snelling Fault zone - should exploration/or data currently being processed prove encouraging.

4. Exploration Target.

The target sought by Preussag Australia Pty. Ltd. on the Perseverance-Bonaventure prospect is stratiform Pb-Zn(-Cu) mineralization within the phyllite/metasiltstone unit. No economic potential is assisgned to the base metal bearing quartz veins emplaced along the Cygnet-Snelling Fault Zone. This mineralization is considered to have been mobilized from the phyllite/metasiltstone unit during faulting and regional metamorphism.

Yours faithfully,
PREUSSAG AUSTRALIA PTY. LTD.

J.H. Hill,
Manager.

DUPLICATE.

CONTENTS

SUMMARY

Exploration Licence (E.L.) 221 on Kangaroo Island is held by Preussag Australia Pty. Ltd. to assess its potential for stratabound (stratiform) base metal mineralization in the Cambrian Kanmantoo Group. Several old base metal workings are known although the nature and significance of this mineralization have not been fully evaluated.

The location and physiography of the E.L. are described in relation to Kangaroo Island as a whole.

The findings of previous geological work on Kangaroo Island by South Australian Department of Mines and University of Adelaide personnel are discussed, together with the results of base metal exploration programs by former company explorers. Much of the geology of Kangaroo Island is incompletely known and base metal exploration has been limited. Most previous exploration of a detailed nature has been confined to the present area of E.L. 221.

The results of exploration to date by Preussag Australia Pty. Ltd. are summarized and the company's future work program outlined. A Pb-Zn soil anomaly has been established surrounding the old Perseverance-Bonaventura workings and warrants further work. Additional reconnaissance along the Cygnet-Snelling Fault Line is planned.

INTRODUCTION

Exploration Licence (E.L.) 221 was secured by Preussag Australia Pty. Ltd. ffom the South Australian Department of Mines to investigate the potential of the Cambrian Kanmantoo Group on Kangaroo Island for ?Kuroko and Mt. Isa types of base metal mineralization. Base metal mineralization (essentially Pb-Zn and Cu) was known to occur in several localities within the area at the time of application. However, the nature and significance of this mineralization was unknown.

It was considered that an Exploration Licence would enable assessments of the known mineralized localities to be carried out and the Kanmantoo Group generally to be examined with the aim of locating stratabound (stratiform) base metal mineralization of ?volcanogenic affinities.

E.L. 221 was granted for an initial term of three months with tenure commencing on 25 November 1975. The term has subsequently been extended for an additional three months.

LOCATION AND ACCESS

E.L. 221 is located in the northern coastal region of Kangaroo Island. The E.L. is 576 square kilometres in area and is bounded by longitude 136°45', longitude 137°25', latitude 35°45', a line 800 metres inland from high water level along portion of the northern coastline and the boundaries of the Cape Torrens and Western River Conservation Parks.

Kangaroo Island is a large, settled land mass adjacent to the southern coastline of South Australia. The principal settlement on the island is Kingscote, which is approximately 120 kilometres from Adelaide by sea. The shortest direct route from the mainland to the island lies between Cape Jervis and Penneshaw across Backstairs Passage, a distance of approximately 20 kilometres. No townships lie within the area of E.L. 221. The nearest is Parndana, which is situated near the southern boundary. The island generally is elongate in shape with approximate maximum dimensions of 140 and 55 kilometres east-west and north-south respectively.

Kangaroo Island is served by daily, commercial air services between Adelaide and Kingscote. Light aircraft services also operate regularly into the townships of Penneshaw, American River and Parndana. A rollon-rolloff vessel, the M.V. "Troubridge", sails three times weekly between Adelaide and Kingscote and is the principal means of supply for the island. The E.L. is well served by a network of unsealed roads and access to most localities is relatively simple. Exceptions however are to some sections of the northern coastline which are extremely precipitous.

CLIMATE, PHYSIOGRAPHY AND LAND USE

Kangaroo Island is generally cooler in summer and warmer in winter than the mainland. Temperature variations in any season also tend to be less. Most rainfall is received in the winter months between May and September. Rainfall decreases from west to east across the island, from approximately 800mm on the west coast to 550mm at Kingscote. In all seasons, south-west winds dominate the wind system. Prolonged bad weather in winter often affects the southern coastline.

The greater part of the island is occupied by a plateau which is flat and poorly drained. The plateau is terminated by high cliffs along the northern coastline and by a belt of low-lying country along the south coast. The area held by Preussag Australia Pty. Ltd. contains both deeply incised, coastal and flat, plateau regions. Soils are mostly lateritic podsols, yellow-brown sands and sandy loams above mottled clays. Iron-stone or ferricrete gravels typify these soils. Organic and alluvial soils are found in the stream valleys along the north coast where drainage is northerly towards the sea.

In the higher rainfall portion of the island, tall eucalypts are numerous together with varied, and often dense, scrubby vegetation. Where rainfall is lower, mallee scrub forms dense growth from three to seven metres in height. Farming developments have led to the clearing of much of this vegetation but essentially untouched regions do remain.

Farming and tourist activities are the principal sources of income for the island. Wheat, barley, wool and beef are the main farm products, while Kingscote, American River and Penneshaw are the most important tourist resorts. Fishing is also of some importance. Gypsum is currently obtained from salt lakes on Dudley Peninsula and salt has also been worked. Beach sands at Nepean Bay are being worked on a small scale for their contained heavy minerals. However, only farming activities are pursued within E.L. 221.

PREVIOUS INVESTIGATIONS

Geological

Geological map coverage of the island is limited. The only published sheet (Kingscote 1:253,440) is that of Sprigg in 1954 (Ref. 15). However, the geology shown on this sheet requires extensive revision in the light of new proposals re the stratigraphy of the Cambrian Kanmantoo Group. Relatively recent mapping has been carried out by Daily and Milnes of the University of Adelaide (Refs. 6, 7) and Major and Vitols (Ref. 11) of the South Australian Department of Mines. Dudley Peninsula and the western, coastal portion of the island were mapped by these groups respectively. However, Daily and Milnes have only published the geology of the northern coastline of Dudley Peninsula to date. Thomson (Refs. 12,13) has shown generalized interpretations of the geology and structure of the island. The Barker 1:250,000 geological map sheet also contains a portion of the geology of Dudley Peninsula (Thomson and Horwitz, Ref. 14).

South Australian Department of Mines workers have generally utilized a threefold division of the Kanmantoo Group into the following formations:

Strangway Hill (base)
Inman Hill
Brukunga (top)

The Brukunga Formation has been further subdivided into the Nairne Pyrite Member (lower) and Brown Hill Greywacke Member (upper).

Daily and Milnes (Ref. 8) have erected a more comprehensive stratigraphy for the Kanmantoo Group which has been adopted by the writer.

Daily (Ref. 5) has correlated the essentially unmetamorphosed and shallow dipping Cambrian sequence on the north coast of the island near Emu Bay with units of the Kanmantoo Group.

Daily, Twidale and Milnes (Ref. 9) have assigned ?Triassic and Jurassic ages respectively for the ferricrete and flatlying basalt which are present on the island.

Mineral Exploration

Previous exploration by other companies which is directly relevent to the Preussag Exploration Licence has been carried out by:

1) Elchor Australia Pty. Ltd. - SML 252 (Ref. 10)
2) A.O.G. Minerals Pty. Ltd. - SML 688 = E.L.61 (Ref. 1)
3) Aquila Investments Corp. Ltd.
   John Liddy Associates Ltd. - SML 702 = E.L.86 (Ref. 2)

Of the three, only A.O.G. Minerals Pty. Ltd. proceeded to the stage of detailed exploration with gridding, soil sampling, geophysics (I.P.), mapping and diamond drilling (four holes). The other two companies were involved with stream sediment sampling only.

Elchor Australia Pty. Ltd. held virtually all of Kangaroo Island per S.M.L.'s 252 and 253 during the period November '68-April '70. A large part of the present area of E.L. 221 was tested by stream sediment sampling. A.O.G. Minerals Pty. Ltd. followed up stream sediment Pb-Zn anomalies which had been established by Elchor Australia Pty. Ltd. but not further investigated. Aquila Investments Corp. Ltd./John Liddy Associates Ltd. also assessed the results of Elchor's sediment sampling but follow up work was very limited.

An area of approximately 500 square kilometres within S.M.L. 252 was stream sediment sampled by Elchor Australia Pty. Ltd. and 3,219 samples collected. The -80 mesh size fraction was utilized for analysis following orientation work in the vicinity of the Western River Pb-Zn workings. Threshold and anomalous values were assigned as follows (all p.p.m.):

Metal	Threshold	Possible Anomaly 1-2 x Threshold	Probable Anomaly 2-3 x Threshold	Definite Anomaly
Cu	40	40 - 79	80 - 119	120 & >
Pb	70	70 - 139	140 - 209	210 & >
Zn	90	90 - 179	180 - 269	270 & >

This work essentially located one major zone anomalous for Pb (principally) and Zn and as well, reflected the presence of old mine workings. Following the initial survey, some check stream sediment sampling was carried out together with very limited rock sampling (11 samples). Some rock samples were collected from the major anomalous zone which was to be re-investigated later by A.O.G. Minerals Pty. Ltd. Values to 0.34% Pb, 0.11% Zn and 180ppm Cu were obtained in these samples. However, Elchor Australia Pty. Ltd. did not extend its exploration program and S.M.L. 252 was surrendered.

A.O.G. Minerals Pty. Ltd. confirmed the presence of the major Elchor anomaly while holding S.M.L. 688 (=E.L.61). The anomaly was designated the Dewrang Prospect by this company. Reconnaissance soil sampling on a random basis then gave Pb values in the range 20-1800ppm in the anomalous zone. Copper and Zn values were "not high" and generally inconclusive. An area of 2,800 metres by 800 metres was subsequently gridded and sampled at 100 metre intervals. Values in the range 30 - 3,200ppm Pb resulted. Zinc values were much lower than those of Pb and although Zn "highs" were roughly coincident with Pb "highs", no direct correlation was possible. Copper values were generally insignificant although above background values were also roughly coincident with anomalous Pb(-Zn) values. An arcuate zone approximately 1,600 metres in length by 200-300 metres in width was defined by the 250ppm Pb contour. Within this zone, three pronounced local "highs" of 2,600, 2,700 and 3,200ppm Pb occurred. The peak Cu value of 320ppm did not coincide with high Pb and Zn values (only 380 and 200ppm respectively).

Further closely spaced soil sampling (411 samples) was then carried out by A.O.G. to more accurately define the most anomalous portions of the arcuate zone. This work effectively divided the zone into a number of "spot highs, small lenses and interfingering tongues" but did not indicate definite drill targets. Twelve samples of the 411 were analysed spectro-

graphically for a selection of elements. Barium and Ti in the ranges 200 to 1,000ppm and 4,000 to +10,000ppm were the only results of note.

An east-west trending sequence of phyllites, metasiltstones and metasandstones was mapped within the A.O.G. grid. Petrographic work revealed the presence of galena as very fine inclusions within grains of goethite (after ?pyrite). Trace sphalerite, galena and chalcopyrite were also noted in the heavy mineral concentrate of one soil sample which contained 1.20% Pb and which was collected during the follow-up soil sampling.

A.O.G. Minerals Pty. Ltd. drilled four diamond drill holes after an I.P. survey had outlined a number of anomalies. Details of the drilling are summarized in the table below:

Hole no.	Declination:	Depth in metres:
1	45° S	75.13
2	44° N	88.55
3A	50° S	56.08
3B	55° S	100.10
4	52° S	79.99

Hole 1 was sited to test a combined I.P./soil anomaly (Pb 3,000ppm). Phyllite and metasandstone were the principal rock types intersected together with narrow, pyritic beds which contained very fine galena and sphalerite on joints and fractures. Carbonaceous partings also occurred in both phyllite and metasandstone. However, Pb and Zn values did not exceed 500 and 5,800ppm respectively in the sections of core which were analysed. Hole 2 was also sited on a combined I.P./soil anomaly (2,000ppm Pb) and intersected highly weathered rock with fine limonite bands after ?pyrite. Cavernous, Fe stained quartz also occurred over one 10 metre section of core. No sulphides were identified and no core was analysed. Two attempts were made to drill Hole 3 which was sited to test the Hole 2 locality below the zone of weathering. Phyllite and metasandstone were intersected with minor pyrite on joints and foliation planes. No core was analysed. Hole 4 tested a soil anomaly (3,000ppm Pb) which had no coincident I.P. anomaly.

Similar lithologies to those in Holes 1 - 3 were encountered. Sulphides occurred as pyrite on joints and foliation planes and as fine grained galena, sphalerite and pyrite in quartz filled fractures. Values to 1,000ppm Pb and 1,200ppm Zn were obtained.

Petrographic work on selected A.O.G. drill core specimens determined that very fine grained base metal sulphides occurred in marcasitic lamellae conformable with bedding and in discordant fractures and quartz veinlets. Some remobilization and concentration of trace to minor amounts of Pb, Zn, Cu sulphides which occur in narrow bands of fine grained, pyritic sediment was postulated. This process presumably took place during the low grade metamorphism which has affected the rocks.

Aquila Investment Corp. Ltd./John Liddy Associates Ltd. assessed the results of the earlier stream sediment sampling program by Elchor Australia Pty. Ltd. and outlined three anomalies within S.M.L. 702 (E.L. 86):

1) 2.5 - 3 kms. west to southwest of Western River Station . . . . Pb/Zn
2) 2 - 4 kms. west of Middle River Station . . Pb/Zn/Cu
3) 2 kms. north and NNE of Middle River Dam . . Pb/Zn

Followup work appears to have been extremely limited, however.

Several companies have explored for base metals in other parts of Kangaroo Island. ASARCO (Australia) Pty. Ltd. (Ref. 3) sought Cu-Mo mineralization in altered granitic rocks near the southern coastline and on Dudley Peninsula (S.M.L.'s 520 and 521 respectively). Beach Petroleum N.L. (Ref. 4) explored for base metal mineralization in pyritic-pyrrhotitic metasediments of both Proterozoic and Cambrian age on Dudley Peninsula (S.M.L. 628). This company utilized the recent geological findings of Daily and Milnes in its work. The sulphide-rich horizons, which are well exposed along the northern coastline to the east of Penneshaw, had earlier been extensively sampled by ASARCO Australia Pty. Ltd. A.O.G. Minerals also further investigated a small Mo anomaly which had been initially located by ASARCO within S.M.L. 520.

~~011~~
017

Deposits of salt, gypsum, clay and heavy mineral beach sands also occur on Kangaroo Island but not within E.L. 221. Clay deposits occur in weathered granite on Dudley Peninsula and have been worked on a small scale. Gem quality chalcedony, beryl and tourmaline have been obtained from a pegmatite on Dudley Peninsula and similarly at Daws Diggings near Parndana. Only very small numbers of reasonable quality stones have been won. Heavy mineral beach sands are currently being worked on a small scale adjacent to Nepean Bay.

GEOLOGY

The table below summarizes the known stratigraphy of Kangaroo Island. On the limited information available, only Kanmantoo Group rocks are believed to be present within E.L. 221. However, the possibility that Proterozoic-Adelaidean rocks are present should not be discounted at this stage. Daily and Milnes (Ref. 6) have mapped rocks of this age on Dudley Peninsula and Proterozoic rocks are also shown by Sprigg on the Kingscote map sheet. Lower Cambrian carbonate rock types do not occur within the E.L. on knowledge to date.

Kangaroo Island stratigraphy

Age	Rock unit	Lithology
QUATERNARY		alluvial and colluvial sand, clay and gravel; beach and dune sand; swamp and lagoon saline clay and sand; aeolianite with shell bed (Stokes Bay) and conglomerate (Kingscote) plus calcrete; marshy, saline flats near Kingscote with shell beds.
TERTIARY		
- EOCENE		bryozoal limestone
MESOZOIC		
- JURASSIC		columnar, vesicular basalt
- ?TRIASSIC		massive and pisolitic ferricrete (laterite); associated ferruginous sand, clay & gravel.
PALAEOZOIC		
- PERMIAN		glacial till; fluvioglacial clay, sand and gravel; isolated erratics.

Age		Rock unit	Lithology
- CAMBRIAN	KANMANTOO GROUP	Younger Kanmantoo Group	phyllitic and arenaceous metasediments.
	Inman Hill Sub Group	Tapanappa Formation	metasandstone and minor phyllite; some conglomerate bands; thin sulphide bands.
		Talisker Calc-Siltstone	calcareous phyllite and meta-siltstone; thin sulphide bands.
		Backstairs Passage Formation	metasandstone.
		Carrickalinga Head Formation	phyllite, metasiltstone, metasandstone.
	NORMANVILLE GROUP	Wangkonda Limestone	impure marble.
		Mount Terrible Formation	meta-arkose, metasiltstone, siliceous calc-silicate rock with pyrite/pyrrhotite.

(younger Normanville Group rocks are not present at Sprigg Inlet due to faulting)

PROTEROZOIC			
- ADELAIDEAN	MARINO GROUP		metasiltstone, andalusite schist, quartzite, gritty marble.
	STURT GROUP	Brighton Limestone	marble.
		Tapley Hill Formation	laminated metasiltstone and phyllite; some sulphide rich bands (pyrite/pyrrhotite)
		Sturt Tillite	metasiltstone, quartzite, meta-arkose, metamorphosed boulder bed (tillite); some sulphide-rich bands (pyrite/pyrrhotite).

Note: Rocks of the Sturt, Marino and Normanville Groups are mapped only on Dudley Peninsula to date.

Unmetamorphosed Cambrian rocks occur in the northern coastal region of Kangaroo Island near Point Marsden. Daily (Ref. 5) has correlated these rocks with Kanmantoo Group units.

Within E.L. 221, good outcrop is generally only located near the coastline. Large areas of ferricrete and soil obscure folded

Cambrian rocks further inland.

At the western end of the island, Kanmantoo Group rocks have been folded into a series of shallow plunging synclines and anticlines. Fold axes trend approximately northeast-southwest. Similarly oriented, large scale structures occur within the Preussag E.L..

Major normal and thrust faults have been mapped within the area. These are the Snelling-Cygnet and Cassini faults respectively. Most of the known examples of base metal mineralization are closely associated with the former structure.

Metamorphism in the Kanmantoo Group (and ?older) rocks increases from east to west across the area and reaches andalusite grade at the western end. Metamorphic grade also generally increases from north to south across Kangaroo Island and migmatites are encountered near the southern coastline. Here too, granitic rocks outcrop in several localities. Daily and Milnes (Ref. 8) consider that similar intrusive rocks on the mainland near Victor Harbour were emplaced prior to the main phase of deformation of the Kanmantoo Group sediments in the Kanmantoo Trough. Intrusion occurred at the highest known stratigraphic level of the Group (Wattaberri Sub-Group).

Large, vertical movements provided material for the developing Kanmantoo Trough in which rapid deposition occurred. Deep water conditions are not envisaged by Daily and Milnes (Ref. 8). Rather deposition appears to have kept pace with subsidence. The movements persisted throughout much of the Group's depositional history as reflected by the presence of conglomerate bands in units younger than the Tapanappa Formation. The influence of a source area to the north of Kangaroo Island (Yorke Peninsula vicinity) is shown by the presence of boulders of Proterozoic-?Carpentarian rocks (crystalline basement types) and Lower Cambrian Archaeocyatha limestone in the White Point Conglomerate. This unit is unmetamorphosed and outcrops on the northern coast of Kangaroo Island (approximately 10 kilometres NNW of Kingscote).

Orogenic movements of Cambro-Ordovician age deformed the Proterozoic and Cambrian rocks of Kangaroo Island and were

preceded (and ?accompanied) by the granitic intrusions mentioned above.

MINERALIZATION

Old mine workings within E.L. 221 are summarized below. All known base metal workings on Kangaroo Island occur within the E.L. In addition, pyritic quartz veins have been worked for their Au contents in some localities. All base metal workings are small and obviously only minor production has taken place.

Snug Cove Pb-Ag(?Zn)

Workings: ?1 shaft

Production: ?

Grade: ?

Mineralization: galena in ?quartz vein

Host rock: ?phyllite

Western River Pb-Zn-Ag

Workings: 3 groups, several shafts and pits, 2 adits, 1 open cut.

Production: ?

Grade: 50% Pb, 8 oz/ton Ag, ?Zn

Mineralization: galena plus sphalerite in E-W trending quartz vein (?fault zone).

Host rock: biotite metasiltstone

Bells Pb-Ag

Workings: 2 shallow pits (believed to be prospecting venture only)

Production: -

Grade: -

Mineralization: galena plus pyrite in veinlets

Host rock : brecciated and heavily fractured fine grained marble.

A.O.G. Pb-Zn amomaly

- no workings but 4 d.d. holes.

Minor galena plus trace sphalerite and chalcopyrite in fractured metasiltstone and phyllite; mineralization in pyritic laminae parallel to bedding and in veinlets (remobilized) - for further details see earlier.

Perseverance Pb-Zn-Cu-Ag-?Au

Workings: 1 shaft, several shallow pits

Production: ?

Grade: ?% Pb, to approx. 40% Zn, 12 dwt/ton Ag, trace Au

Mineralization: galena, sphalerite and chalcopyrite in fractures and with quartz.

Host rock: metasandstone

Bonaventura (Graingers, Blue Gum Hill) Cu-Ag-?Au

Workings: 1 shaft, several pits

Production: known 40 tons ore raised

Grade: to 10% Cu

Mineralization: chalcopyrite with quartz

Host rock: phyllite, metasiltstone.

Cygnet (Tiłkas) Au

Workings: 1 shaft, several pits

Production: ?

Grade: average 2 - 5 dwt/ton Au

Mineralization: Au with pyrite and ?arsenopyrite in quartz vein

Host rock: chloritic phyllite-metasiltstone; also gritty arkosic rock present.

Rainbows End Au

Workings: several shafts, open cuts and pits plus 1 adit

Production: ?

Grade: average 1.5 dwt/ton Au

Mineralization: Au with Fe oxides (ex-pyrite) in quartz veinlets

Host rock: brecciated quartz chlorite rock (metasiltstone,)

PREUSSAG INVESTIGATIONS

The following details summarize work to date on E.L. 221 by Preussag personnel.

Research - available information re the known geology, mineralization and previous exploration on Kangaroo Island has been researched and summarized.

Geochemistry -

a) stream sediment sampling
   - 121 samples collected
   - washed -20+80 fractions pulverized and analysed for Cu, Pb, Zn.

b) soil sampling

- 564 samples collected; includes 177 non grid-based and 387 grid-based samples (see below)
- 28 of 387 grid-based samples collected during an orientation survey to determine optimum sampling depth
- grid sampled essentially on 50 metre centres with some closer sampling as well
- samples crushed and splits of same pulverized prior to analyses for Cu, Pb, Zn

c) rock chip sampling

- 28 samples collected
- samples crushed and splits of same pulverized prior to analyses for

Cu, Pb, Zn Ag	:	28 samples
Mn	:	12 samples
Co	:	1 sample

Note : In a), b) and c) above, all analyses were carried out by A.C.S. Laboratories of Unley, South Australia.

Gridding -

- 13,000 line metres pegged prior to soil sampling (plus additional 2800 metres unpegged but soil sampled)
- grid 2.4 kilometres east-west x 1.0 kilometres north-south; 13 north-south lines with spacings of 200 metres; pegs at 50 metre intervals.
- grid surrounds the old Perseverance Pb-Zn(-Cu) and Bonaventura Cu workings (approximately 4 kilometres ESE of the Dewrang Prospect the former explorer A.O.G. Minerals Pty. Ltd.)

Geophysics -

- preliminary ground magnetic survey (total magnetic intensity) of 7000 line metres of the soil grid.

Petrography -

- four samples described by I.R. Pontifex & Associates of Rose Park, South Australia.

Geology - reconnaissance over the E.L.

Initial work by Preussag personnel on E.L. 221 consisted of stream sediment, soil (non grid-based) and rock chip sampling plus geological reconnaissance. The principal aim of this work was to evaluate the results obtained by former explorers,

to hopefully establish a stratabound nature for the known base metal mineralization and to assess the potential of the E.L. for further exploration.

The initial work led to the selection of a small area around the old Perseverance-Bonaventura mine workings for more detailed study. Gridding, soil sampling and a preliminary ground magnetic survey then followed. A Pb-Zn soil snomaly has been outlined which warrants additional work.

Map sheets have not been included in this report. The preparation of final drafts of all relevent sheets is currently in progress. These sheets plus complete tabulations of data will be included in the second quarterly report.

FUTURE PREUSSAG WORK

It is anticipated that the following activities will be carried out in the second quarter:

1) detailed mapping of the existing grid
2) infill soil sampling on the grid (100 metre line spacings) to allow closer definition of the Pb-Zn anomaly
3) additional reconnaissance along the Cygnet-Snelling Fault Line.

Any additional work would be determined by the results obtained from this program.

A.J. Hosking,
Geologist.

PREUSSAG AUSTRALIA PROPRIETARY LIMITED

EXPLORATION LICENCE 221
KANGAROO ISLAND
SOUTH AUSTRALIA, AUSTRALIA

SECOND QUARTERLY REPORT
TO
24TH MAY, 1976

SUMMARY.

Exploration by Preussag has been concentrated on the Perseverance - Bonaventura prospects. Work consisted of soil and rock geochemistry, geological mapping with associated petrographic investigations, and the results are presented in this report. A geochemical Pb-Zn soil anomaly occurs in a phyllite - metasiltstone - metasandstone sequence adjacent to the Cygnet - Snelling Fault. Quartz veins carrying to minor amounts of pyrite and base metal sulphides cut the metasediments. No evidence for stratabound base metal sulphides within the finer grained metasediments has been found.

The results of initial Preussag exploration in EL.221 are contained in this report, as are details of previous, relevant exploration by other companies.

.../2

INTRODUCTION.

The location of EL.221 is shown in Fig.1.

The following activities were completed during the period:-

1. Geological mapping of the Perseverance - Bonaventura prospects at 1:5,000.

2. Infill soil sampling on the Perseverance - Bonaventura grid (160 samples).

3. Rock sampling at the Rainbow's End and Cygnet Gold Mines.

.../3

PREVIOUS INVESTIGATIONS.

The stream sediment data of Elchor Australia Pty. Ltd. has been utilized. Tabulations of this data are presented in Figs. 2 - 5. Anomalous and weakly anomalous zones for copper, lead and zinc are shown. One definite anomaly located by Elchor was later investigated by A.O.G. Minerals Pty. Ltd. (Dewrang prospect). Other, less substantial, anomalies were also outlined but not tested.

The soil geochemical data of A.O.G. Minerals Pty. Ltd. for the Dewrang prospect is summarized in Figs. 6 and 7. Diamond drill hole locations are also shown, together with anomalous I.P. zones (Fig. 8). The soil data is included for the purpose of comparison with that from the Perseverance - Bonaventura prospects.

.../4

CURRENT INVESTIGATIONS.

The following is a summary of work by Preussag Australia Pty. Ltd. within EL.221.

GEOCHEMISTRY:-

- 936 samples collected; viz.:-

  stream sediment - 127
  soil - 725
  rock chip - 84

GEOLOGY:-

- Geological reconnaissance throughout the tenement using 1:50,000 and 1:25,000 air photo coverage.

- Geological mapping at 1:5,000 over the Perseverance-Bonaventura grid.

GEOPHYSICS:-

- 7,000 line metres of the Perseverance - Bonaventura grid covered by an orientation ground magnetic survey (total magnetic intensity).

PETROGRAPHY:-

- 10 rocks have been petrographically studied.

GRIDDING:-

- 14,800 line metres pegged on a 200 metres x 50 metres grid surrounding the old Perseverance and Bonaventura workings.

GEOCHEMISTRY:-

a) Stream Sediment Sampling.

Analytical data is summarized in the Table below. The results of six (6) samples collected during initial reconnaissance are not included.

TABLE I.

STREAM SEDIMENT SAMPLING DATA.

Range of Values (ppm)	No. of Cu Values.	No. of Pb Values.	No. of Zn Values.
0 - 20	111	55	42
25 - 40	10	36	47
45 - 60	-	18	15
65 - 80	-	4	6
85 - 100	-	1	6
110 - 200	-	4	4
210 - 300	-	3	1
	121	121	121

.../5

An orientation programme was completed for -20 + 80 and -80 fractions in both anomalous and background ranges. Washed -20 +80 fractions were analyzed.

The stream sediment sampling was utilized to check the results of Elchor. Repeat sampling by Preussag failed to confirm several anomalies. Some anomalies are located within the 800 metre coastal strip which is to be protected from mining. Some re-sampling has been completed to assist in the evaluation of the Preussag data. Anomalies are mainly due to the presence of quartz veins carrying Pb-Zn sulphides.

Other anomalies reflect the presence of pyritic, black shales, similar to those found at the Dewrang and Perseverance - Bonaventura prospects. Some weakly anomalous values are due to variation of outcrop density between the northern, coastal region,where outcrop is good, and the southern, "plateau" region, where clay soil and ferricrete predominate. Elchor data should be first divided into "coastal" and "inland" populations prior to detailed stratistical treatment being attempted.

The location and metal values of all Preussag stream sediment samples are shown in Figs. 10-12.

b) Soil Sampling.*

TABLE II.

SOIL SAMPLING DATA.

*) The results of 28 orientation samples (H1434-H1461: see Appendix 1) from six auger hole soil profiles and two isolated samples are not included in the above tabulation. /c

Orientation sampling at the Perseverance workings indicated that lead values decreased with increasing depth in the soil profile (decrease from 400 ppm to 200 ppm illustrated by five (5) samples collected over two (2) metres from a pit near the workings). However, later sampling (H1434 - H1461) demonstrated the reverse situation; e.g., an increase from 1000 to 2000 ppm Pb over one (1) metre (also an increase from 490 to 1000 ppm Zn over this interval). Consequently, soil samples from the Perseverance-Bonaventura grid were collected using power and hand augers. Most samples were collected at depths ranging from 50-100 cms (unless sited on virtual outcrop). In most instances, weathered rock fragments were included in the samples taken from the main zone of interest within the grid.

The first soil sampling programme sought to test for extensions to east and west of the soil anomaly of the Dewrang prospect. Soil traverses were necessary because of poor outcrop. Sampling demonstrated that further work in this prospect was not warranted. However, an area surrounding the old Perseverance and Bonaventra workings warranted additional exploration.

The locations of the first programme sample lines and tabulations of metal values are shown in Map 12. The results of the first soil sampling (and stream sediment sampling) in the Perseverance-Bonaventura area are also shown in Map 14.

Grid-based soil sampling in the Perseverance-Bonaventura area has outlined a soil anomaly 750 metres east-west x 250-400 metres north-south (as defined by the 250 ppm Pb contour). Contours of Cu, Pb and Zn values are shown in Maps 15-17. The anomaly is derived from finely crystalline and brecciated quartz veins, carrying trace to minor amounts of pyrite, galena and sphalerite, and a phyllite-metasiltstone which probably contains trace to minor amounts of stratabound base metal sulphides. Float from weakly mineralized quartz veins and differential preservation of quartz fragments in soil are believed to have enhanced both and size and strength of the anomaly. Trace amounts of very fine grained chalcopyrite were detected by A.O.G. in diamond drill core of carbonaceous shale-metasiltstone from the Dewrang prospect. The general low copper values in soil samples from both the Dewrang and Perseverance-Bonaventura prospects may be due to strong leaching during the formation of ferricrete bearing soils.

c) Rock Chip Sampling.

Most rock chip samples were collected from the Perseverance-Bonaventura prospect. Analytical data is plotted in Maps 9-13 and 18.

Samples of vein quartz containing finely dispersed galena and sphalerite from the Perseverance-Bonaventura prospect confirm the values obtained in soil samples (particularly Pb).

.../7

The only other metal values of note occur in material collected from dumps at the Rainbow's End Gold Mine (higher than average Cu values and one Au value of 15 ppm).

GEOLOGY:-

The tenement was secured to assess the potential of the Kanmantoo Group for base metal mineralization. The only potentially favourable host rock consists of dark, carbonaceous, pyritic phyllite and metasiltstone. These rocks have been intersected in diamond drill holes on the Dewrang prospect by A.O.G. Minerals Pty. Ltd. and, although not known in outcrop on the Perseverance-Bonaventura prospect, are believed to exist here also. Similar rocks extend westwards from the Dewrang prospect.

Phyllites, metasiltstones and metasandstones make up the Kanmantoo Group. Regional metamorphism is evident over wide areas, however, in the eastern portion north of the Cygnet-Snelling Fault Line, the rocks are virtually unmetamorphosed and weakly folded.

Mapping and soil sampling of the Perseverance-Bonaventura prospect was completed at 1:5,000 (Map 20).

Examination of diamond drill core from the Dewrang prospect confirmed the presence of cross-cutting and conformable pyrite bands. However, galena was not positively identified while coarse-grained sphalerite was only detected in irregular quartz veinlets and on fracture planes.

GEOPHYSICS:-

A ground magnetic survey (total magnetic intensity, Map 19) was completed over the Perseverance-Bonaventura prospect to determine whether slightly magnetic ferricrete would eliminate magnetics as a tool. The uncorrected data shows some correlation with soil anomalies.

PETROGRAPHY:-

The location of dump material containing lead and zinc sulphides at the Perseverance workings resulted in the investigation of the Perseverance-Bonaventura area by the Company. This material (H1312: see Appendix 2) was initially described as a "volcanic breccia". However, subsequent petrographic work did not confirm this.

Later petrographic work also confirmed possible metasomatic alteration (quartz-tourmaline) at both Perseverance-Bonaventura prospect and the Rainbow's End Gold Mine.

Ten samples have been petrographically described (Appendix 2).

.../8

CONCLUSIONS.

Investigations indicate little potential for economic base metal sulphide mineralization.

.../9

RECOMMENDATION.

It is recommended that no further investigations are justified and the tenement be surrendered.

Submittal No 1.

H 1312 Volcanic breccia of sericitic potash felspar crystal tuff and epithermal quartz; mineralised in interfragmental areas with sphalerite subordinate quartz accessory galena and pyrite.

This rock has a gross, fairly coarse breccia texture, composed mainly of a random, loosely packed aggregate of angular potassic fragments up to 20mm across (highlighted by staining). The subordinate interfragmental areas are occupied mainly by sphalerite (15-20%) and quartz (7-10%).

The potassic domains consist of a fairly well sorted, but massive detrital aggregate of generally subangular grains of potash felspar, average grain size 0.3mm. These are fairly loosely packed with a very fine intergranular matrix which is extremely difficult to identify but appears to consist of clay-sericite, chlorite and chloritic clays with minor extremely fine potash felspar, quartz and plagioclase. The coarse potash felspar grains are clouded by minor clay-sericite alteration. This aggregate is interpreted to be a volcanic lastic sediment almost certainly of direct volcanic derivation (i.e. a potash felspar crystal tuff).

Minor irregular patches grading imperceptibly into the potash felspar aggregate consist of fine quartz mosaic made up largely of incipient euhedral (prismatic) quartz crystals, and is characteristic of massive quartz mineralisation of epithermal or volcanogenic origin.

H 1312 contd.

The patchy nature of these quartz aggregates suggests an overall breccia, rather than tuff suggested above.

Irregular and apparently interfragmental areas between these potash and lesser quartzose domains are occupied by coarse aggregates of sphalerite, intimately mixed with lesser, quite coarse, stressed vein quartz, and accessory sphalerite are scattered through the felsic and finer quartzose host rock.

In polished section accessory very fine galena (1%) and pyrite (1%) are seen sporadically distributed in fairly close association with sphalerite, less commonly as independent grains in the host rock.

The objective petrographic evidence indicates that this is a mineralised potassic-siliceous tuff-breccia with all components probably having a common origin. More specifically it is a breccia of sericitised and weakly chloritised potash felspar crystal tuff and volcanogenic quartz aggregate, mineralised in interfragmental areas.

H626a Kangaroo Island

Schmittal Nos. 2 & 3.

H626a: breccia of meta arkose (of "granitic" origin); epithermal quartz-sphalerite-galena mineralisation throughout interfragmental areas

This rock has a gross breccia texture, composed of a loosely packed aggregate of angular fragments commonly measuring up to 10 x 30 mm, with quartz sulphide mineralisation throughout interfragmental areas.

The fragments consist of an essentially micro-granoblastic ("quartzitic") aggregate of essential quartz and potash felspar grains, average grain size 0.15 mm. Minor sericite and lesser fine chlorite occurs along inter-granular boundaries throughout the aggregate. Accessory detrital zircon, muscovite and tourmaline are present.

The brecciated rock is interpreted to be a meta-arkose derived from a "granitic" terrane. There is no positive evidence of volcanic contribution to the original sediment, although some relict rounding in occasional quartz grains, which barely survive the metamorphic textural modification, may be original phenocrysts.

Areas between fragments are occupied mainly by vein quartz, composed of randomly interlocking fine subhedral to euhedral crystals, characteristic of epithermal mineralisation. This quartz penetrates the fragments to varying degrees, confusing their composition and texture.

Irregular patches of honey colored sphalerite up to 10 mm across, with closely associated, subordinate patches of galena are sporadically distributed through the vein quartz, and rarely form veinlets on their own. Trace minute grains of pyrite occur independently, but commonly in the vicinity of the main sulphides.

H626 b,c K-Island (Perseverance)

[redacted]

Submittals 4 & 5

H 626 b : metamorphically recrystallised and brecciated potassic arkose; veins of quartz galena and trace sphalerite

This is a massive, brecciated but otherwise fairly homogeneous fine "quartzitic" rock with random veins of mainly galena, and some drusy quartz along fractures.

In thin section the domains between fused and/or mineralised fractures are seen to have an irregular, but generally fairly homogeneous microgranoblastic texture, average grain size about 0.2 mm. They consist of essential quartz and potash felspar with minor to subordinate plagioclase (albite). The quartz and microcline in particular, show evidence of stress and grain boundary re-crystallisation to form the present texture. These various components have a very even distribution, essentially as independent grains throughout the aggregate -- a feature highlighted by examining the yellow stained potash felspar in the offcut block.

Trace fine muscovite and chlorite are scattered. The interfragmental areas are occupied mainly by micro crystalline vein quartz of characteristic epithermal texture, and this tends to permeate the fragments bounding the fractures, contributing to the silicification and fusion to the aggregate (in addition to the recrystallisation). Galena and lesser sphalerite occurs in some veins.

..../

626 b contd.

The rock is interpreted to be a metamorphically recrystallised felsic (arkosic) sediment of "granitic" composition. The fracturing is tectonic and superimposed, although conceivably occurred during metamorphism. The mineralisation is later and may represent a final phase of tectonic reconstitution; its source is not known.

The rock is essentially the same as H626a described in report 1840 although it contains considerably more plagioclase. In retrospect there seems no positive evidence to indicate that this rock has a volcanogenic history, as suggested for sample H1312 (report 1823) from the same locality. Almost certainly the sediment derived from an acid igneous source, and closer consideration of the mineral assemblage, including the apparently largely microcline composition of the potash felspar, notably in H626 and H626c, suggests a plutonic rather than volcanic source.

H 626 c : massive, fine grained, arkose, fairly extensive intergranular clays after detrital felspar

This is a massive, homogeneous, fine grained meta arkose with a similar essential mineralogical composition to H626 b. However it is more friable and shows negligible evidence of brecciation and/or associated silicification; i.e. it is far less texturally modified than samples 626 (b), or 626, or 1312.

The essential detrital aggregate consists of potash felspar and quartz in about equal abundance, minor plagioclase (?20%), and accessory detrital muscovite flakes, minute detrital opaque iron oxide grains and trace detrital tourmaline. About 1/3 of the potash felspar is microcline.

These components have a random but very uniform distribution, average grain size about 0.2 mm. What is now intergranular clays (30%), ± fine sericite appears to be mainly derived from former detrital felspar grains, but why some felspars are extensively altered in this way and others virtually unaltered is not clear.

The alteration is conceivably due to weathering. This rock is a non-brecciated and virtually unmineralised equivalent of 1312, 626 and 626 b (although a small patch of galena occurs on the exposed surface). It is a homogeneous well sorted arkosic sediment which as discussed for H626 b is probably of granitic derivation. Certainly there are no diagnostic features of a volcanic origin.

I R Pontifex

PONTIFEX & ASSOCIATES PTY. LTD.

H2494: muscovite-quartz schistose hornfels (meta-sediment); minor apparently metasomatic quartz-biotite ± accessory tourmaline; trace ?pyrite pseudomorphs

This rock has a combined schistose to hornfels metamorphic texture. It consists of a sheared-out, stressed microgranoblastic mass of quartz with abundant, variably continuous foliae and attenuated network of fine muscovite (25-30%). Lesser greenish-brown biotite (7-10%) is more randomly distributed commonly in clumps along roughly cross cutting fractures. Accessory fine tourmaline grains and small clumps of these more or less accompany this biotite. Poorly defined, discontinuous (introduced) quartz "veins" accompany some biotite; this is also largely discordant but locally occurs along the "schistosity" merging with the quartz hornfels mosaic. Relatively finer and coarser bands can be identified in the quartz mosaic, and almost certainly reflect original bedding; minor patches of recrystallised quartz appear to represent original quartzose clasts or coarse grains. There is no positive evidence of original volcaniclastic components however.

The rock is interpreted to be a muscovite quartz schistose hornfels, formed by extensive recrystallisation of an argillaceous quartz silt to fine quartz sandstone. The biotite tourmaline and vein quartz domains appear to be introduced conceivably by metasomatic agencies.

Trace limonite replicas after a group of several ?pyrite crystals are present.

H2495: medium grained, thin bedded arkose with essential muscovite-sericite matrix; characterised by intercalated heavy mineral layers of hematite, lesser tourmaline, monazite, zircon

This is a fairly homogeneous, thin bedded, medium grained sandstone, characterised by abundant laminae and/or fine layers of detrital heavy minerals. The non heavy mineral layers consist of a loosely packed aggregate of subangular quartz and an almost equal abundance of plagioclase grains, average and fairly consistent size 0.2 mm. This aggregate has an essential matrix of fine muscovite and/or sericite mixed with silt size quartz and felspar. This is probably an essentially metamorphic matrix, although the generaly randomness of the micas indicates lack of shearing stress, and suggests the possibility of some hydrothermal alteration.

The heavy mineral grains have a similar size to the quartz and felspar, and a similar micaceous matrix. They consist mainly of corroded-looking (opaque) hematite grains, variety martite, which formed by oxidation of former magnetite. However monazite, zircon tourmaline, form about 20% of the total heavy minerals, and trace apatite rutile and ? xenotime are also present.

The rock is essentially a micaceous arkose with abundant heavy mineral bands, the mineral assemblage suggests a provenance of a high-level granitic terrane, charged with pegmatitic domains. Conceivably potash felspar from such an area has given rise to the muscovite-sericite matrix.

H2504: plagioclase sericite chlorite quartz shale, somewhat indurated, several carbonate potash felspar veinlets;
(metamorphosed argillaceous siltstone)

This is a homogeneous, very fine grained rock with a clearly defined cleavage coincidental with original bedding. It consists of a tightly packed aggregate of quartz and minor plagioclase grains of silt to fine sand size, with a more or less intergranular matrix of chlorite, sericite and ultra fine quartz.

The matrix components occur in fine shredded streaks to form the cleavage; they represent metamorphically recrystallised argillaceous material.

Accessory fine tourmaline, extremely fine, clouded, secondary titania minerals, and trace spots of indigenous carbonate are scattered. Several veinlets of carbonate ± subordinate potash felspar cut the rock. These appear to have been introduced from an external source.

There is no evidence of volcaniclastic components.

H2506: lineated quartz-tourmaline "hornfels"

The mineralogy of this rock is quite simple, it consists entirely of quartz and tourmaline in approximately equal abundance. The quartz has a fairly homogeneous granuloblastic texture (polygonal mosaic), average size 0.2 mm.

Tourmaline is scattered in discontinuous layers and attenuated network, as ragged aggregates of crystals up to 0.5 mm. The tourmaline is variably very dark green (near opaque) to pleochroic from biscuit color to dark grey-green. Rare bluish green zones occur in some crystals.

Objectively the genesis of such a rock is difficult to determine but three possibilities are suggested:-

1. A sheared and recrystallised mass of boron-silica metasomatic mineralisation, which may result from complete tourmalinisation of slates and pelitic hornfelses, or possibly complete autometasomatism of a parent granite.

2. A recrystallised sediment composed of quartz and tourmaline, conceivably locally derived from a ?pegmatitic domain of this composition (unlikely).

3. A volcanic exhalative deposit.

It is noted that facies of similar composition are reported from Rosebery (Tasmania) but I do not know its relationship to volcanics in that area. Also I have heard of quartz tourmaline lenses in pyritic chert of probable volcanic origin.

H2508: medium grained thin bedded (potash felspar) arkose with minor sericitic matrix; minor heavy mineral bands of mainly hematite

Macroscopically this is similar to H2495, although with lesser heavy mineral layers; petrographically (and in the stained off-cut) it is differentiated by virtue of lesser intergranular matrix, and by essential potash felspar, rather than predominantly plagioclase in H2495.

The rock consists of a fairly tightly packed, well sorted aggregate, of subangular, detrital, grains of essential quartz, potash felspar and minor plagioclase. Average grain size is 0.3 mm. This aggregate has a sericitic intergranular matrix which varies from 5-7% in some layers to 20% in others.

The bedding is locally warped and/or buckled; this is a primary sedimentary feature and in the section examined it is well displayed by a single heavy mineral layer, and by several less continuous laminae in which heavy minerals are relatively less abundant.

The heavy mineral grains are mainly hematite (variety martite), accessory tourmaline and zircon, trace ?monazite and apatite.

It may be hypothesised that this rock represents the same arkose facies as H2495, and that the sericite "matrix" in H2495 is the hydrothermally altered equivalent of its essential contained potash felspar.

H2518: fine, sericitic quartzo-felspathic schist (moderately sheared and recrystallised argillaceous arkose); incipient potash-silica metasomatism; trace disseminated pyrite

This rock consists largely of a loosely packed aggregate of angular to subrounded grains of quartz potash felspar and plagioclase, average and fairly consistent size 0.2 mm. This aggregate has a metamorphically recrystallised matrix of sericite mixed with extremely fine quartz. The sericite defines a fine foliation within the matrix which is oblique to the fine bedding laminations of the coarser grains.

Accessory detrital tourmaline, clouded titaniferous grains and rare detrital ?hematite form very incipient heavy mineral layers.

Poorly defined veinlets of vein quartz and potash felspar locally follow the cleavage, and bedding, and are also at random to these directions. These are interpreted to represent very incipient potash-silica metasomatism of external origin.

Very fine (0.15 mm) grains of pyrite (1-2%) are present; these have no specific or mutually exclusive mode of occurrence, however they do not appear to be detrital, and they do tend to occur adjacent to the introduced potash-silica material. Thus they may be tentatively interpreted to have a related metasomatic origin.

There is no evidence of definite volcaniclastic components; the arkosic character and heavy minerals indicate a related facies to most other rocks in the suite.

Subject: EL 221 - KANGAROO ISLAND

Preussag Australia Pty. Ltd. wish to surrender Exploration Licence 221 - Kangaroo Island.

The tenement is due to expire on 24th November, 1976, and since the date of grant 24/11/75 the Company has expended $18,325 on exploration.

A combined final and third quarterly report is in preparation.

Yours faithfully,
PREUSSAG AUSTRALIA PTY.LTD.

THIRD QUARTERLY AND FINAL REPORT
TO
24 AUGUST 1976

SUMMARY

Exploration Licence 221 was acquired in order to prospect for stratabound base metal mineralization in the Lower Cambrian Kanmantoo Group.

Work completed included stream sediment, soil and rock chip sampling, geological mapping and petrographic studies. The exploration results over the Perseverance-Bonaventura prospect indicated there is no potential for economic base metal sulphide deposits.

RECOMMENDATIONS

It is recommended the tenement be surrendered.

THIRD QUARTERLY AND FINAL REPORT

TO

24 AUGUST 1976

INTRODUCTION

This report discusses exploration programmes completed in previous quarters. The first two quarterly reports summarize the work of former explorers and of Preussag.

The location of Exploration Licence 221 is shown in Figure 1. No fieldwork was completed during the period.

CURRENT INVESTIGATION

The tenement was secured to assess the potential of the Lower Cambrian Kanmantoo Group for volcanogenic base metal mineralization. A number of old workings (lead-zinc, copper and gold) were known to exist at the time of application, however, little recent information on the geology of the area was available and exploration was mainly concerned with establishing whether volcanics were present in the mineralized localities. Initially, stream sediment, soil and rock chip sampling, geological mapping and petrography were utilized to check the results of previous explorers and to obtain relevant information. Arising from this first phase, an area surrounding the Perseverance-Bonaventura Mines was

.../2

selected for further work.

Soil and rock sampling, geologic mapping and a ground magnetic survey was completed in the Perseverance-Bonaventura area. Poor outcrop and extensive cover made investigations difficult. Orientation soil sampling failed to definitely establish the behaviour of metals in soil, ferruginous clay and pisolitic ferricrete cover. Sampling was subsequently completed in the weathered C-horizon between 0.5 and 1.5 metres using power and hand augers.

Diamond drill core from the Dewrang prospect of former explorer A.O.G. Minerals Pty. Ltd., was examined. This prospect is situated approximately four kilometres WNW of the Perseverance-Bonaventura prospect.

RESULTS

Soil sampling has outlined an anomally for both lead and zinc (broadly coincident) surrounding the Perseverance and Bonaventura Mines with approximate dimensions of 750 metres east-west by 250-400 metres north-south, as defined by the 250ppm Pb isorad. A number of "spot highs" occur within the anomaly with maximum values of 2700 ppm Pb and 980 ppm Zn.

Mapping in the Perseverance-Bonaventura area shows the presence of a phyllite-metasiltstone metasandstone sequence cut by finely crystalline (low temperature), transversly faulted, brecciated pyritic quartz veins associated with the major Cygnet-Snelling Fault Zone. The Perseverance (Pb-Zn-Cu) and Bonaventura (Cu) mine workings are located on the veins. The soil anomaly is partly derived from the veins and associated mine workings and partly from

.../3

the finer grained metasediments (? concealed veins).

Some correlation between the Perseverance-Bonaventura soil anomaly and ground magnetic "highs" has been noted.

Initial petrographic work describing volcanic breccias was not substantiated during later investigations and this downgraded the potential of the area.

Cross cutting and concordant pyrite occur within the carbonaceous phyllite and metasiltstone in diamond drill core from the Dewrang prospect. Sparse sphalerite and ?galena lie in fractures and foliation planes.

CONCLUSIONS

Trace to minor, cross-cutting, base metal (Pb-Zn-Cu) mineralization occurs on the Perseverance-Bonaventura and Dewrang prospects. The mineralization is believed to occur in the Talisker Calc-siltstone of Daily & Milnes (ref. 1) due to the presence of thin, carbonaceous, pyritic phyllites and metasiltstones in the Dewrang diamond drill core and of a thin marble band along strike and to the west of the Dewrang sequence.

The sulphides may have been remobilized from carbonaceous shales during diagenesis and regional metamorphism. Remobilized sulphides have been described by George (Ref. 3) in the Nairne Pyrite Member which is equated by Daily and Milnes (ref. 2) with the Talisker Calc-siltstone.

The possibility that the mineralization is metasomatic and related to Ordovician granitic

intrusives must also be considered. Quartz feldspar veinlets occur in the Perseverance Mine adit and quartz-tourmaline hornfels float has been observed near the workings. Ordovician granites crop out to the south of the tenement near the southern coastline of Kangaroo Island where tourmaline bearing rocks are known. Tourmaline metasomatism has also been described from the Rainbows End Gold Mine located on the Cygnet-Snelling Fault, as are the Perseverance-Bonaventura and Dewrang prospects. Volcanics have not been recognized in the tenement.
